

Infection control - TB

Information for clinicians and health workers about infection control for TB

It is important to manage risk of Tuberculosis (TB) infection however this is relatively straightforward.

TB infection control in hospitals and healthcare clinics

When a person presents with a cough or other symptoms of TB, it is recommended that:

- > they wear a surgical mask
- > close contact health workers wear an N95 mask or, if unavailable, a surgical mask

If a person with suspected active TB is in hospital, it is recommended they stay in a single, negative pressure room.

There is no need for environmental disinfecting.

If a health worker has TB symptoms

Any health worker displaying symptoms or who believes they have been exposed to active, untreated TB should stay away from work and undergo testing.

Infection control for patients

If a patient is diagnosed with active pulmonary TB, they will be advised by their doctor what precautions they should take. In particular, they should not share bongs.

Sometimes if a person is sick or the diagnosis is not yet clear, the person may need to be admitted to hospital.
